Main contributions

- We present an analysis of the time consumption of the prediction, update, and resampling steps, respectively, for SMC-MB recursion from the results of Monte Carlo (MC) simulation.
- We use the gating technique for both survival and birth targets to distinguish survival and birth measurements.
- We propose an efficient measurement-driven approach for the SMC-MB filter. The survival measurements are used to update both survival and birth targets, and the birth measurements are used to update only birth targets.
