Outcomes of allograft from donor kidney microthrombi and secondary recipient thrombotic microangiopathy: should we consider loosening the belt?

Key words: **Microthrombus, Thrombotic microangiopathy(TMA), thrombocytopenia, Deceased donor, Kidney transplantation**

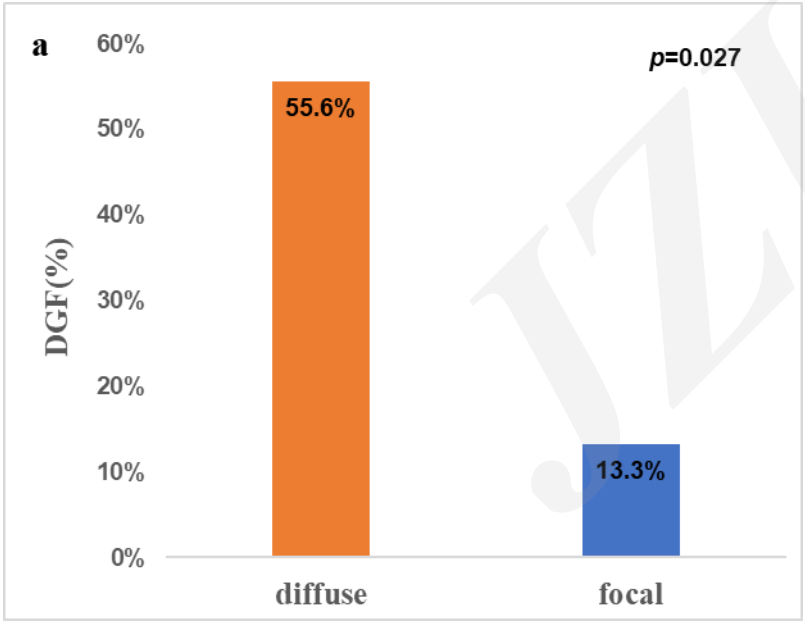

Research Summary

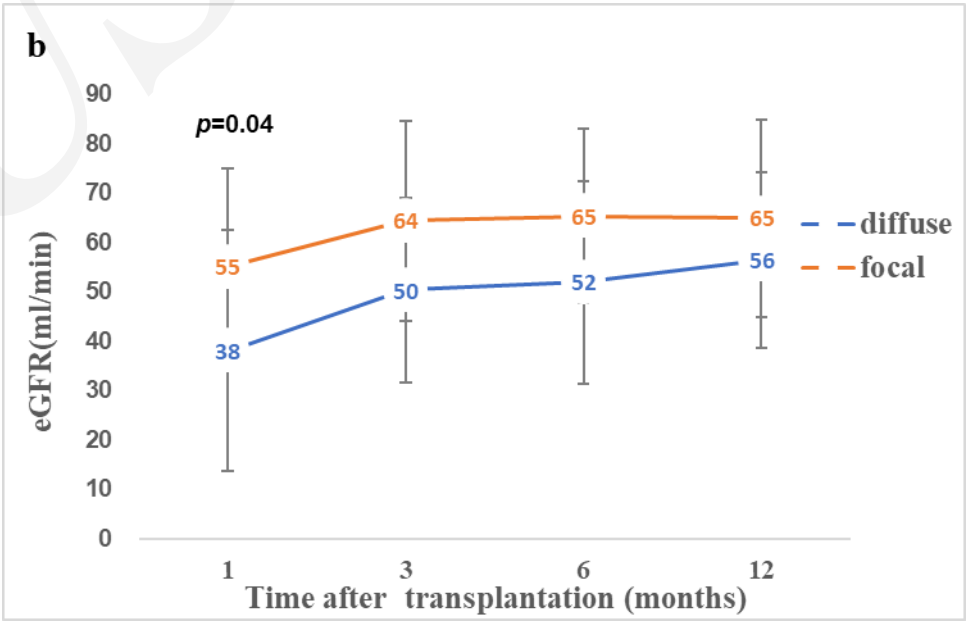

This article mainly focused on the effect of different degrees of microthrombi in donor kidneys and "donor-induced recipient thrombotic microangiopathy"(dir-TMA) on renal function after kidney transplantation.

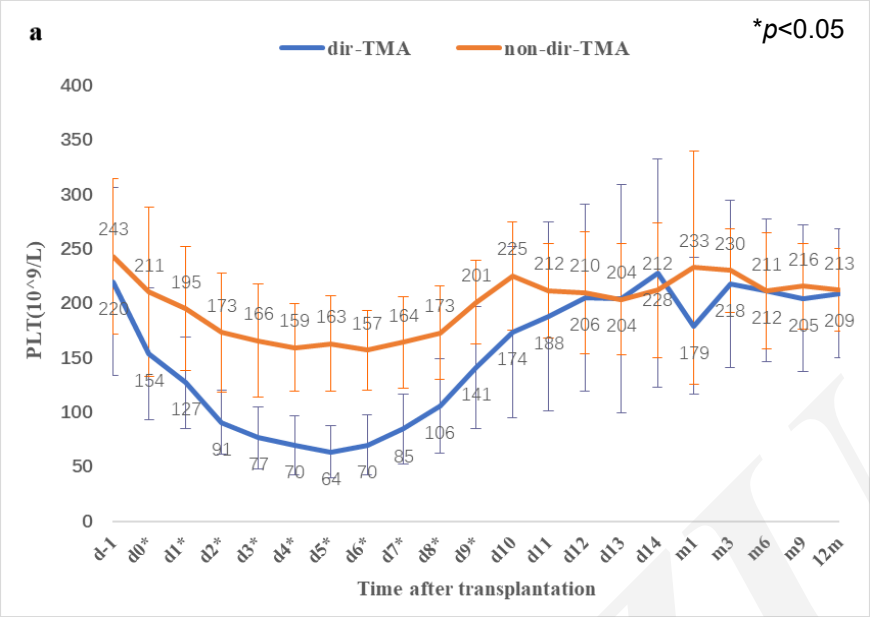

Innovation points

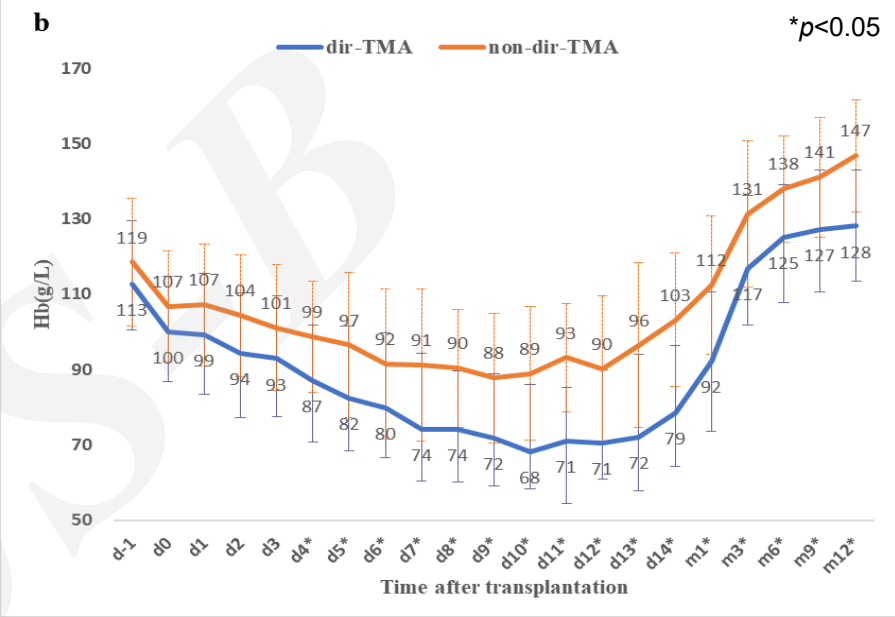

Diffuse thrombi is associated with increased risk of DGF, although it does not affect eGFR.

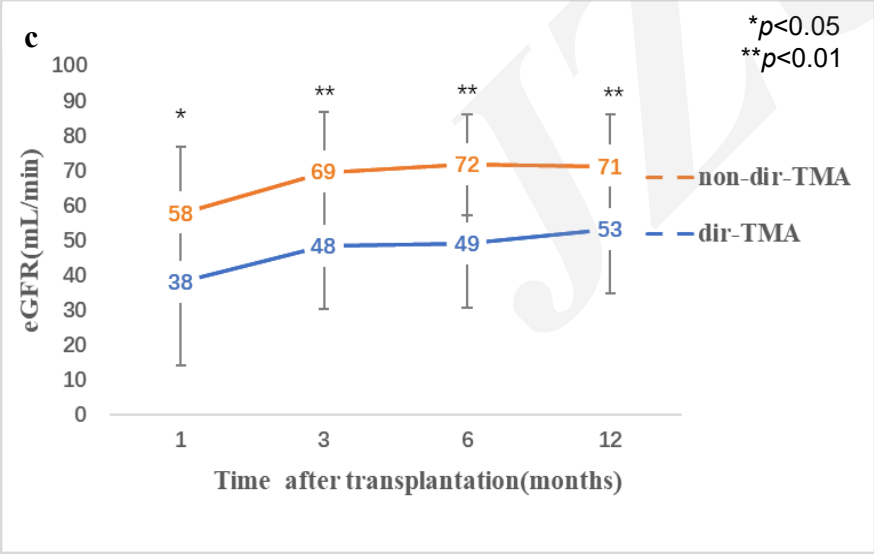

Innovation points

Dir-TMA initiate an early decrease in recipient Hb and PLT, affects long-term allograft function.
