Inflammatory granuloma of the trachea: a rare case with Epstein-Barr virus infection

Key words: Epstein-Barr virus (EBV), Inflammatory granuloma, Metagenomic next-generation sequencing

Innovation points

This unique case report describes a patient developed an inflammatory granuloma in her airway associated with EBV infection.

timeline

Innovation points

Lesson 1

EBV is most commonly transmitted through the respiratory tract. In addition to systemic inflammation, EBV may also play a role in local inflammation.

Lesson 2

EBV may invade the reticuloendothelial cells of the upper respiratory tract and produce inflammatory granulomas. Granuloma caused by Epstein-Barr virus is prone to recurrence.
